WVU IACUC - APPROVED SOP: Superovulation of Female Mice for Embryo Collection

Purpose
The purpose of this SOP is to explain the proper procedures for hormone priming female mice. Hormone priming is used to induce superovulation, thus increasing the number of fertilized embryos for use in services such as transgenic production and the rederivation and/or cryopreservation of mouse strains.

General Information
Young female mice, 3 to 6 weeks of age, are treated with hormones to induce increased follicular development and ovulation. Two hormones, PMSG (pregnant mare’s serum gonadotrophin) and hCG (human chorionic gonadotrophin) are injected intraperitoneally (IP) at timed intervals prior to mating the female with a proven stud male.

PMSG is a hormone found in pregnant mare serum that has follicle-stimulating activity. It is used to induce ovarian follicular development and oocyte maturation.

hCG is a hormone found in human placentas. As it is derived from human tissues, universal precautions should be followed when handling this substance.

Materials and Equipment
1mL sterile, disposable syringes
27-gauge needles
PMSG, 50 IU/mL concentration, frozen -20°C in 1mL aliquots
hCG, 50 IU/mL concentration, frozen -20°C in 1mL aliquots

Timing of Hormone Injections
1. The PMSG and hCG injections should be given 46 to 48 hours apart.
2. The PMSG injection should be given between 1 and 2 pm.
3. The hCG injection should be given between 11 am and 12 noon two days after the PMSG injection.

Recommended Hormone Dosages
The number of embryos collected from a superovulated female mouse may be influenced by several factors including the strain of the mouse, the age of the mouse, the dosage given, the breeding performance of the stud male, and the skill of the person giving the injections. Based on the number of fertilized embryos collected, the hormone dosage can be increased or decreased to maximize superovulation efficiencies. The hormone dosage is usually between 2.5 IU and 5.0 IU.
**Procedures**

1. Hormones should be kept at -20°C until the day of use.
2. WEAR GLOVES when handling the hormones for injection. Do not recap needles.
3. Use a new syringe and needle for each injection.
4. The PMSG and hCG dose for a mouse is 2.5 to 5.0 IU given IP. Start with 5.0 IU and adjust the dosage downward, if needed.
5. To inject a mouse with PMSG or hCG, thaw a vial(s) of 50 IU/ml PMSG or hCG at room temperature or by gently rolling the vial between your hands. Do not shake the vial.
6. Draw 0.1mL of 50 IU/mL (5 IU) into a 1mL syringe with a 27-gauge needle.
7. Restrain the mouse for an IP injection by scruffing the mouse to minimize movement. You may find that tilting the mouse slightly head downward will help as this will move the gut and bladder away from the injection site.
8. Inject into the animal’s lower right (your lower left) quadrant. Draw back on the syringe plunger before injecting to make sure you are not in the bladder or the gut. When drawing back on the plunger, if you see yellow you are in the bladder; red, you have hit a blood vessel; brown or green you are in the gut. If this should occur discard the entire syringe. Load a new syringe and try again. Training is available from OLAR veterinary staff. Contact OLAR directly at 304-293-3737.
9. Discard any unused PMSG and hCG. DO NOT RE-FREEZE.
10. After the hCG injection on day 2, immediately place the hormone-primed female with the designated fertile stud male. Do not have more than one female per male, as this would reduce egg fertilization efficiency.
11. Plug check the female(s) the next morning before 9 am. All females will be used for embryo collection even if a plug is not visible, as the plug may have fallen out.

**Generic answers for some IACUC protocol form questions**

*Name of the procedure:* The superovulation of donor, female mice for embryo collection.

*Details of procedure:* To induce superovulation, donor, female mice will be hormone-primed using intraperitoneal (IP) injections of PMSG, pregnant mare serum gonadotrophin, and hCG, human chorionic gonadotrophin. Following the IACUC-approved SOP for the superovulation of donor female mice, the PMSG and hCG will each be given once. The hCG injection will be given 46-48 hours after the PMSG injection.

*Approximate possible percentage morbidity and mortality due to the described procedure, including likely causes and how they will be addressed.* The intraperitoneal injection procedure utilized for the hormone priming of the embryo donor females is well documented with very few clinical problems reported. We anticipate very good tolerance of the donor females to hormone priming, with less than 1% morbidity and mortality.
